BlockPass

Stellar Instaward Round 1

Completion Report and Customer Development Plan

Submitted to: Stellar Ambassador Chapter Lead

Prepared by: BlockPass team

Date: 6 November 2026

Network: Stellar testnet. Local-currency payments run in a sandbox, and no real money moves.

1. Executive summary

BlockPass is an event ticketing platform for Africa that issues every ticket as a unique, serialized asset on Stellar. This report covers Round 1, a 30-day Instaward to prove that an attendee can choose an event, complete checkout and receive an on-chain ticket automatically.

The minting pipeline, storefront and confirmation flow are built and working on the Stellar testnet. In the final automated run, 24 orders produced 48 unique tickets across 6 events and 8 attendee accounts, and every order was verified independently on Horizon.

Status at a glance

Item	Status	Notes
Deliverable 1: Minting service	Complete	Issuer funding, asset issuance and distribution run on testnet
Deliverable 2: Storefront	Complete, deployment pending	Works on a local build; public URL still to be added
Deliverable 3: Confirmation and logger	Complete	Hash shown to the attendee; every stage logged
20+ test transactions	Complete	24 orders verified on Horizon
2-minute demo video	Complete	Captioned, recorded on a local build
Public repository evidence	Pending	Commit or pull request link still to be added

Beyond the SOW, the team added attendee, organizer and administrator dashboards, detailed event profiles, ratings and reviews, and test-mode payments in local currency or a test stablecoin. Section 6 describes these and their limits.

2. Project overview

The problem

Concerts and community events in Africa often face fake tickets, duplicate screenshots at venue gates and little transparency in ticket sales. Hosts rely on spreadsheets or centralized portals that are open to data manipulation and unauthorized ticket reproduction.

The solution

BlockPass is a two-sided platform. Organizers publish events and track sales, and attendees discover events and receive tickets that can't be copied. Each ticket is a unique Stellar asset with a serial number and a public record, so its authenticity can be checked independently of BlockPass.

Attendees never handle a crypto wallet. BlockPass creates a custodial testnet wallet for each email address, which keeps checkout as simple as any ordinary ticketing site.

Objective of this Instaward

Within 30 days, deliver a functional event storefront and an automated Stellar testnet ticket minting pipeline, where attendees can select an event tier, submit their registration and trigger on-chain asset creation and distribution.

How an order works

Step	Stage	What happens
1	Reserve	One database update takes stock and serial numbers together, so a tier can't oversell and a serial can't repeat.
2	Provision	The event has its own issuer account, and the attendee receives a custodial testnet wallet.
3	Pay	The attendee pays in local currency through the sandbox, or in the test stablecoin on Stellar.
4	Mint	One atomic transaction issues each ticket through the distributor to the attendee. It also carries any stablecoin payment.
5	Record	The order stores the transaction hash, and each stage is written to the server log and database.

Ticket codes are readable. For example, LAGOSV000031 means Lagos Live Nights, VIP, serial 31.

Technology

Layer	Technology
Web application	Next.js, React and TypeScript
API	Node.js, Express and TypeScript
Database	MongoDB
Blockchain	Stellar testnet, @stellar/stellar-sdk, Horizon
Explorer	StellarExpert

3. Deliverable 1: Stellar minting service

What was delivered

A backend service built on @stellar/stellar-sdk that funds issuer accounts through Friendbot, constructs event-specific asset issuance transactions and distributes unique, serialized ticket assets on the Stellar testnet.

- Each event has its own issuer account, created automatically.
- A platform distributor account routes each ticket to the attendee.
- Each ticket is one asset with a supply of 1, capped by trustlines with a limit of 1.
- An order of up to 10 tickets is issued in one atomic transaction.
- Network timeouts and sequence conflicts are retried without risking a duplicate ticket.

Why it matters

This establishes the blockchain foundation for BlockPass, and proves that event passes can be issued reliably and cheaply on Stellar without operational overhead.

A note on Friendbot

Issuers are funded through Friendbot first. Friendbot was often slow during development, so if it doesn't respond, the distributor creates the account directly. Attendee wallets are always created by the distributor, so a buyer never waits on Friendbot. Some demo event issuers were funded through this fallback.

Evidence

Evidence	Location
Issuance and transaction logic	backend/src/services/stellar/ticketAssets.ts (available once merged)
Commit or pull request	**[Add link]**
StellarExpert transactions	Appendix A lists all 24
Sample transaction	ed8b2c6cae508b06…

4. Deliverable 2: Event storefront and checkout

What was delivered

A responsive web interface in Next.js and React that displays event details and ticket tiers, with an attendee checkout form for name, email and quantity. Submitting the form triggers the backend minting service.

Why it matters

It gives reviewers a tangible entry point for testing the purchase flow from an ordinary attendee's perspective.

Evidence

Evidence	Location
Deployed application	**[Add deployed URL]**
Event selection	Figure 1
Event details and tiers	Figure 2
Checkout form	Figure 3
Phone layout	Figure 4

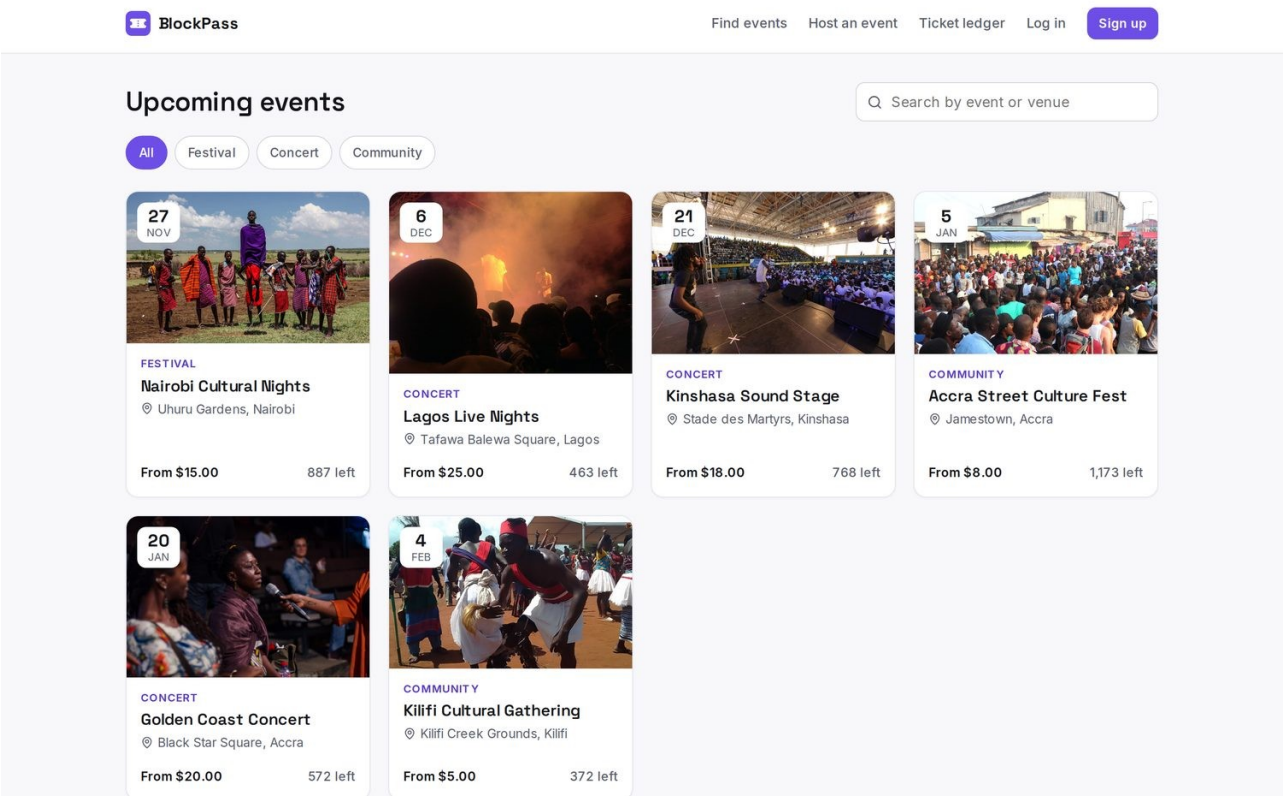

Figure 1. Event selection on the storefront

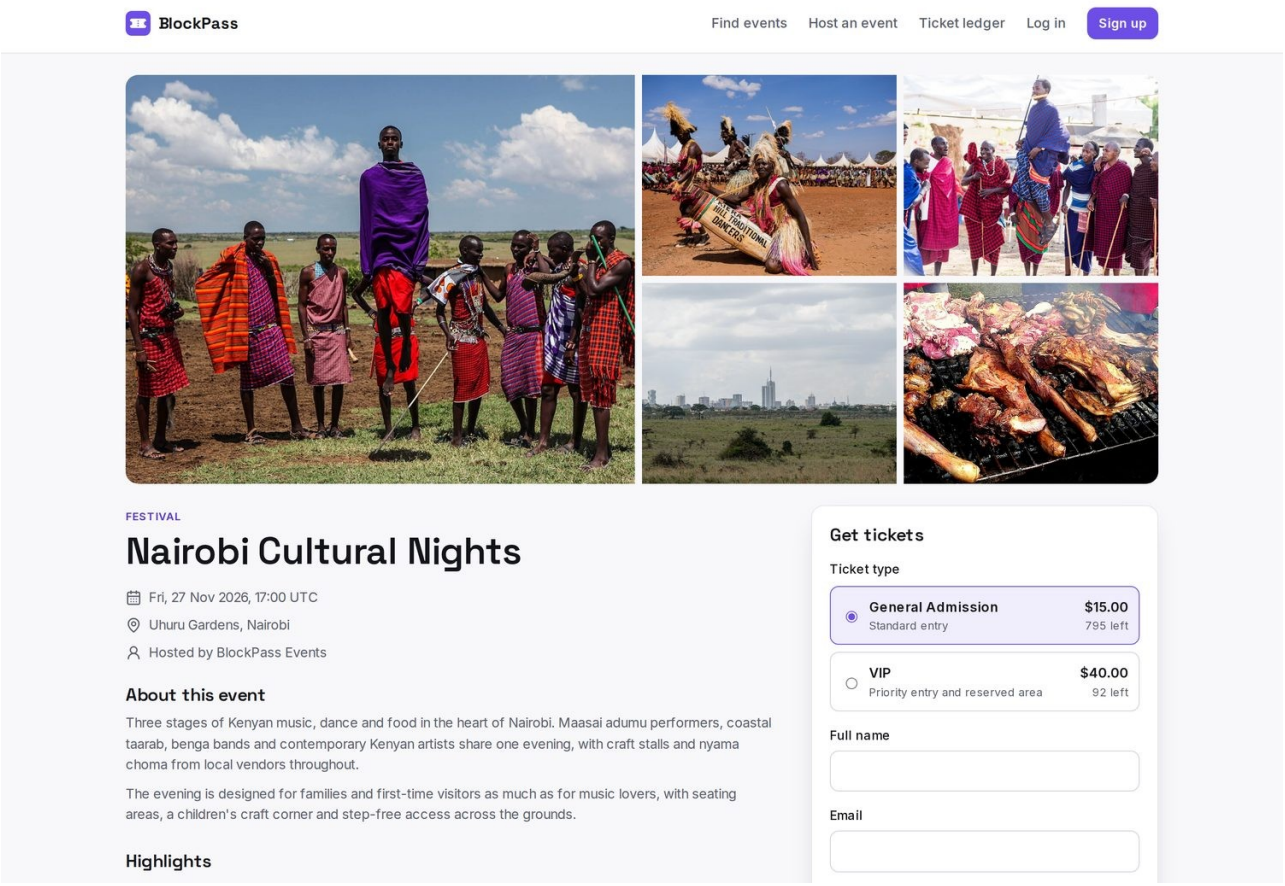

Figure 2. Event profile with gallery, schedule and ticket tiers

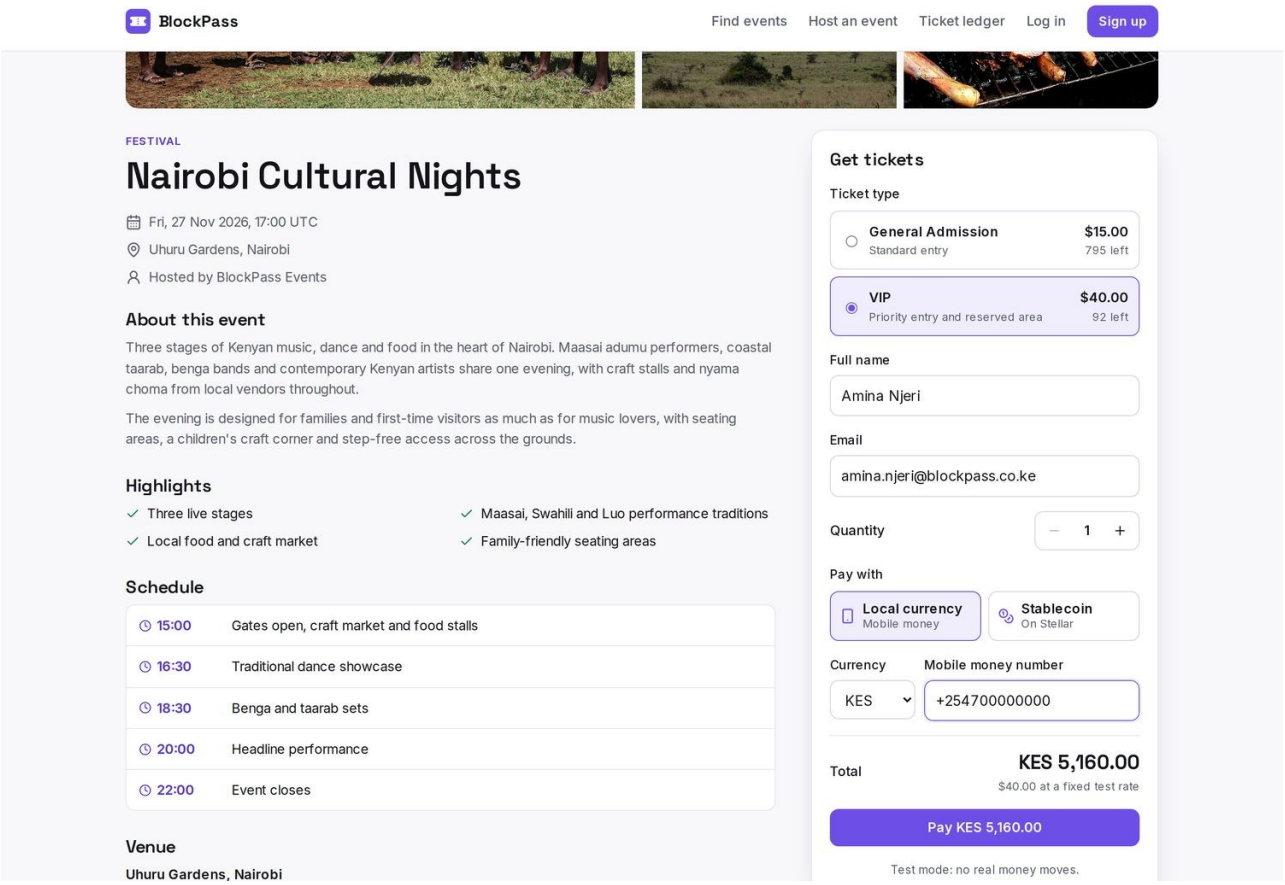

Figure 3. Checkout form with ticket tier, attendee details and payment choice

Figure 4. The event page on a phone

Pages were tested at widths from 320 to 2,560 pixels, with no horizontal overflow on any of the 18 routes checked.

5. Deliverable 3: Confirmation and logging

What was delivered

A confirmation screen that receives the Horizon response, presents the transaction status and hash, and shows each ticket. A backend logger records the issued asset parameters in the database and the server log.

Why it matters

It closes the loop on checkout, verifies that the on-chain mint succeeded and provides traceable hashes for auditing.

Evidence

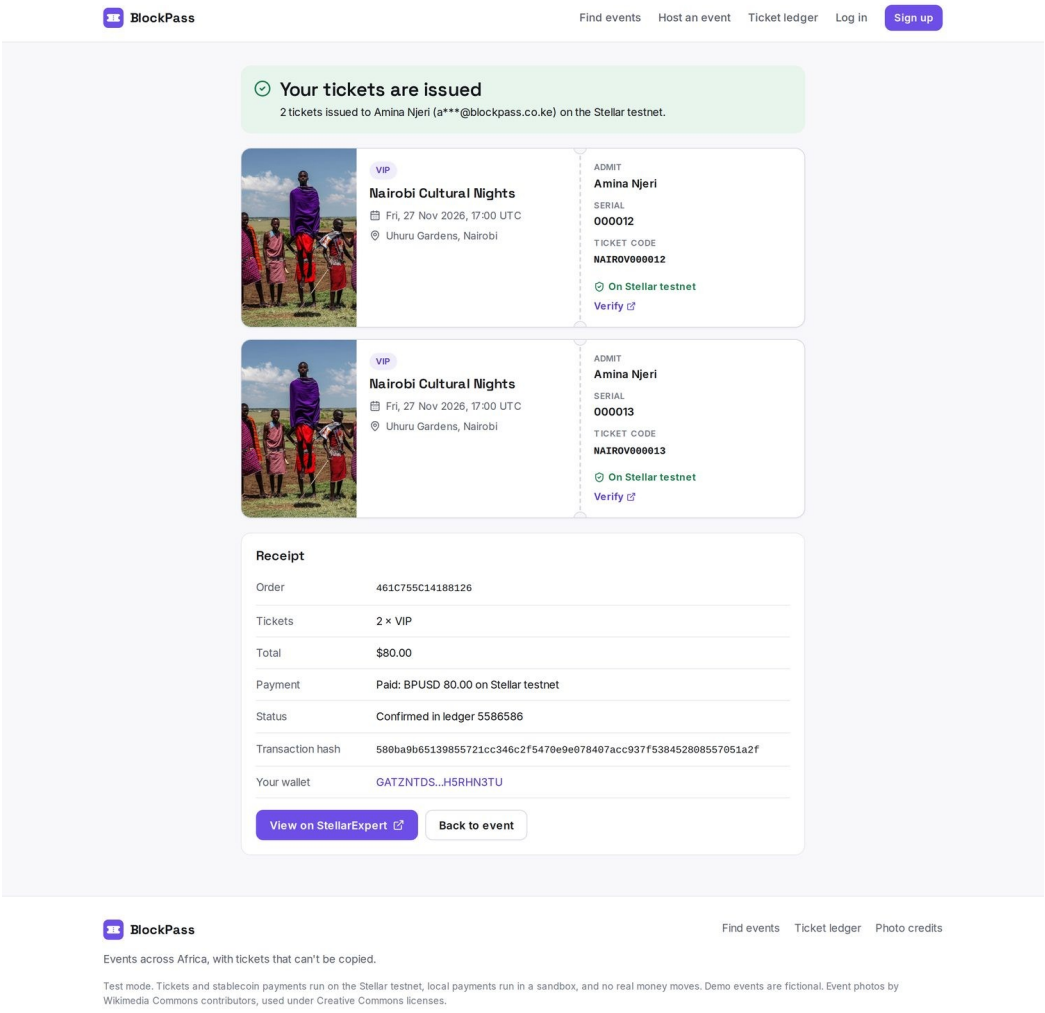

Figure 5. Confirmation screen with issued tickets, receipt and transaction hash

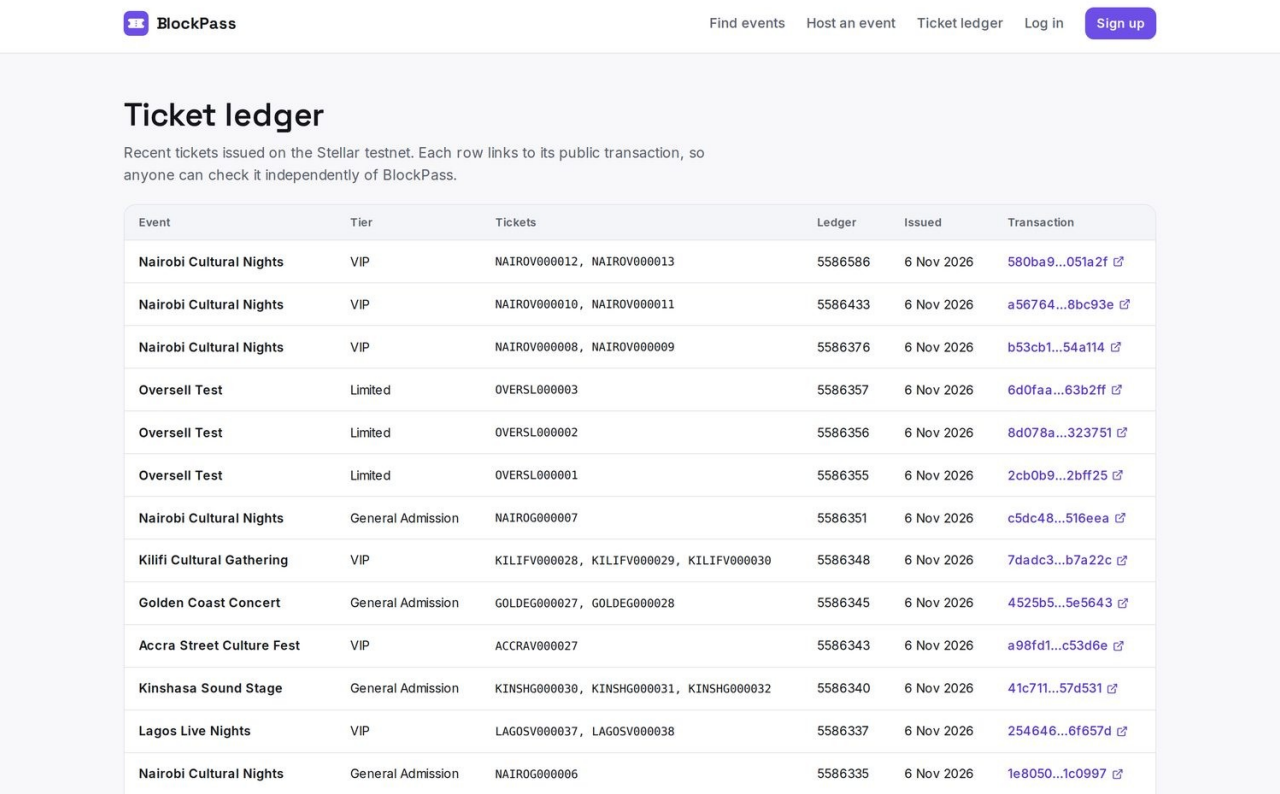

Figure 6. Public ticket ledger, with each row linked to its transaction

Each order writes three stages: order.received, mint.submitted and mint.confirmed, or mint.failed. Attendee email addresses are masked. The file docs/round-one/backend-log-sample.jsonl in the repository contains a complete example.

6. Work beyond the Statement of Work

The following work goes beyond the agreed scope. It is included for transparency and is not needed to satisfy the three deliverables.

Role-based dashboards

- Attendee workspace: tickets, upcoming events and the option to start hosting.
- Organizer workspace: events, sales, attendee lists, CSV export and feedback.
- Administrator workspace: platform totals, minting health, users, event moderation and activity.

Roles are enforced by the API as well as the interface. In testing, attendees and organizers were refused on every administrator endpoint.

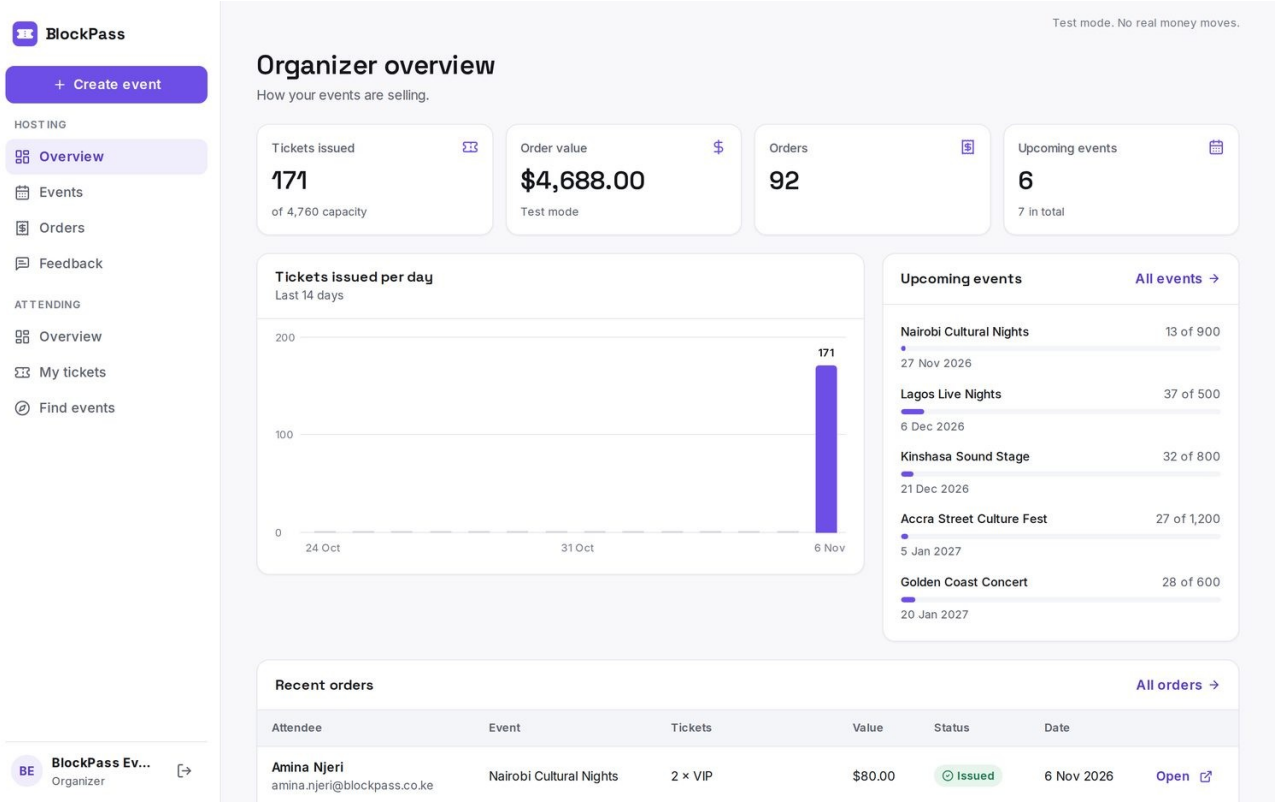

Figure 7. Organizer overview

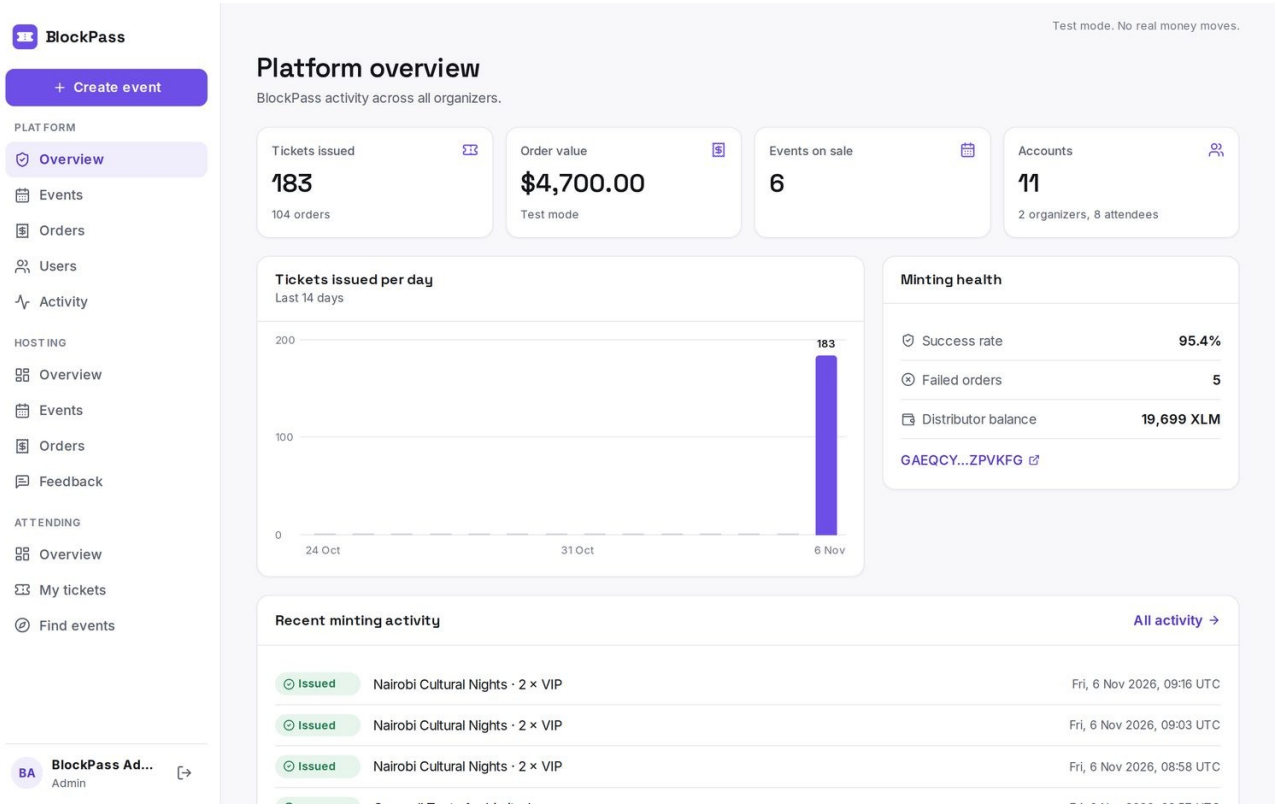

Figure 8. Administrator overview

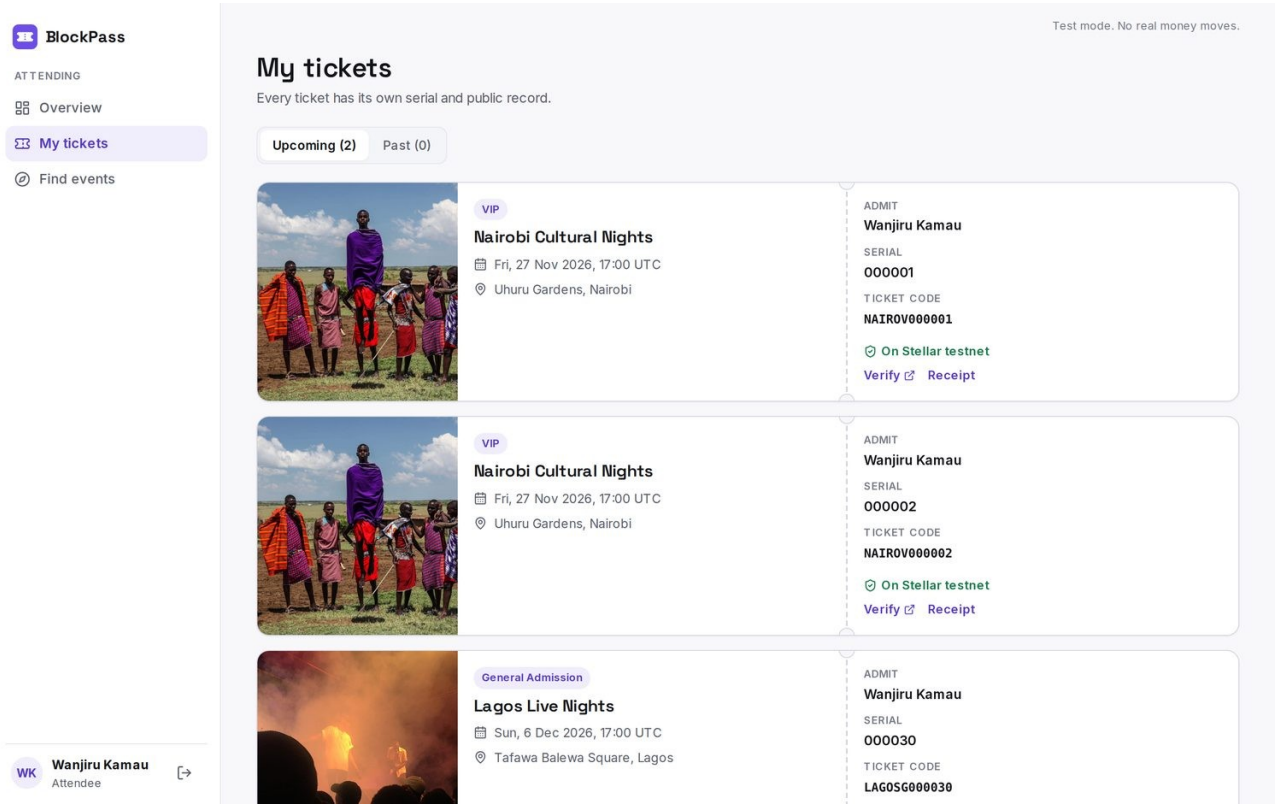

Figure 9. Attendee tickets

Attendee ratings and reviews

Ticket holders can rate and review events, and organizers see the results in a feedback section. The reviews shown in this demo are samples written by the team for a fictional event. They come from real testnet ticket purchases, and each carries a “Sample review” label. They are not customer feedback.

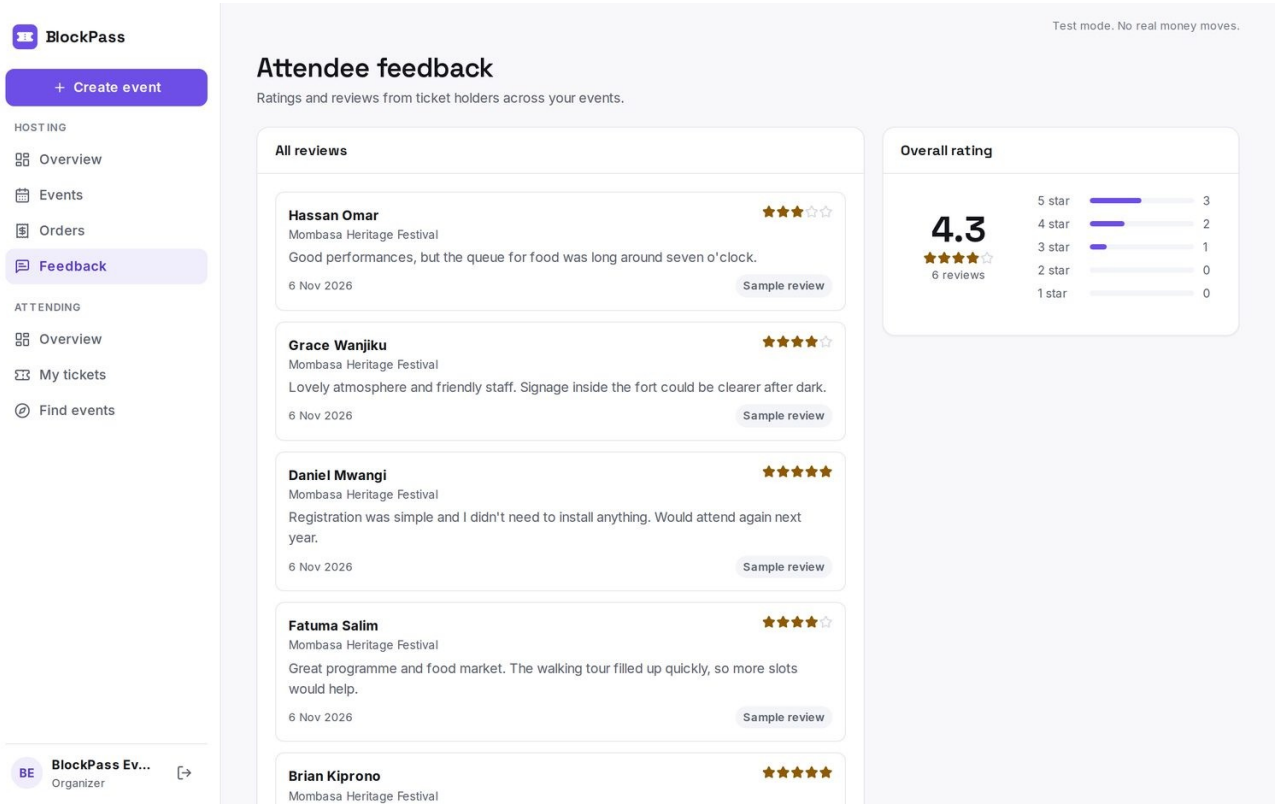

Figure 10. Organizer feedback section, showing labelled sample reviews

Test-mode payments

	Local currency	Stablecoin
How it works	Mobile money form with a choice of 7 African currencies	Paid in the same atomic transaction that issues the tickets
Current state	Sandbox provider that approves every charge	Runs on Stellar testnet with BPUSD, a test asset
Money moved	None	None; BPUSD has no value
Needed to go live	A merchant account with a provider such as M-Pesa or Flutterwave, and a live rate feed	A real stablecoin such as USDC, mainnet deployment, and a way for attendees to fund a wallet

7. Testing and evidence

Final end-to-end run

The script npm run stellar:e2e sends orders through the public checkout endpoint, then checks each one on Horizon rather than relying on the API's own response. The final run covered both payment methods.

Measure	Result
Orders	24
Tickets issued	48
Attendee accounts	8
Event issuers	6
Ledger checks	Transaction successful, memo matches, attendee holds exactly 1, supply is exactly 1

Behavior checks

Check	Result
Every issued ticket is unique	Passed
A double submit returns the same order and mints once	Passed
5 concurrent buyers for 3 tickets: 3 issued, 2 refused	Passed
Invalid orders are rejected	Passed
Both payment methods were exercised	Passed
A forced mint failure releases the reserved stock	Passed
33 access control checks across roles	Passed
5 unit tests for asset codes and transaction construction	Passed

The administrator view reports 5 failed orders in the demo database. Four came from an unfunded stablecoin issuer during development, which was found and fixed, and one was a deliberate failure test. Their stock was released, as designed.

8. Delivery against the 30-day plan

Week	Planned work	Output	Status
1	Repository, environment and Stellar SDK core	Script that creates and funds testnet accounts (npm run stellar:setup)	Done
2	Asset issuance and serialized ticket logic	Backend function that mints a ticket and returns a Horizon hash (npm run stellar:mint-demo)	Done
3	Storefront UI and checkout integration	Web UI that triggers on-chain minting	Done; deployment pending
4	Confirmation flow, testing and documentation	24 test orders, demo video and this report	Done; repository link pending

Out of scope, as agreed

- Mobile ticket view, dynamic QR codes and offline pass storage
- Organizer gate scanner and on-chain redemption or burn at the gate

9. Customer development plan

This is a forward-looking plan. Round 1 was a technical build, so the assumptions below have not yet been validated with customers. All targets are goals for the next phase, not results.

Goal

Learn whether organizers of small and mid-sized events will move their ticketing to BlockPass, and what they need to do so, before investing in mainnet and live payments.

Customer segments

Segment	Who they are	Why start here
Community event organizers (first focus)	Universities, churches, cultural groups and meetups hosting 100 to 500 people	Fast decisions, little existing tooling, and low risk for a pilot
Independent promoters	Concert and festival promoters hosting 500 to 5,000 people	Feel fraud most directly and sell the most tickets
Venues	Halls and grounds hosting recurring events	One relationship can bring repeat events
Attendees	Urban ticket buyers, mostly on phones and mobile money	They must find the experience as easy as what they use today

The first market is Nairobi, where the team can meet organizers in person. Lagos and Accra follow once the approach is proven, in line with BlockPass's Africa-wide focus.

Hypotheses to test

#	Hypothesis	How we'll test it	Supported if
1	Fake or duplicated tickets cost organizers real money	Organizer interviews	8 of 15 report a recent incident
2	Reconciling sales is a bigger daily pain than fraud	Organizer interviews, review of current tools	It ranks in their top two problems
3	Attendees value proof of authenticity but won't accept extra steps	Attendee interviews, checkout tests	80% finish checkout unaided
4	Organizers will pay a per-ticket fee	Pricing conversations during pilots	3 organizers agree to a paid second event
5	Mobile money is required, and stablecoins are a useful option	Payment choice during pilots	Measured share of each method

Discovery interviews

Hold 15 organizer interviews and 30 attendee interviews, using open questions about recent events and not about the product. Each interview is logged in a shared tracker, and findings are reviewed every two weeks.

- Tell us about the last event you ran. How did you sell and check tickets?
- What went wrong? What did it cost you in money or time?

- What have you tried to fix it? Why did you stop?
- Who decides which ticketing tool you use, and how much do you pay today?

Pilot program

Run 3 small pilot events with design-partner organizers, at no cost and on testnet or with live payments once a provider is approved. Pilots start after the gate scanner is ready, because organizers will need to check tickets at the door.

Measures of success

Measure	Next 90 days (target)	How measured
Organizer interviews completed	15	Interview tracker
Attendee interviews completed	30	Interview tracker
Design-partner organizers signed	5	Signed letters of intent
Pilot events run	3	Admin dashboard
Checkout completion rate	80%	Product analytics
Tickets issued in pilots	500	Ticket ledger
Organizers who return for a second event	2 of 3	Admin dashboard

Timeline

Period	Focus	Output
Days 1 to 30	Recruit through the Stellar chapter, universities and community groups; run interviews	Interview findings and ranked problems
Days 31 to 60	Refine the product from findings; sign design partners; build gate scanning	5 design partners and an updated roadmap
Days 61 to 90	Run 3 pilots, gather feedback and test pricing	Pilot report and a decision on next steps

Risks

Risk	Response
Crypto is unfamiliar or distrusted	Lead with verified tickets, and keep the technology in the background
Organizers stay with spreadsheets or WhatsApp	Offer free pilots and hands-on setup
Payment provider approval takes time	Start the merchant application early, with sandbox testing in the meantime
Regulation of digital assets and personal data	Take legal advice on stablecoin payments and custody in each market before going live

10. Limitations and next steps

Current limitations

- Everything runs on testnet, and no real money moves.
- The demo events are fictional, and the photos don't show those events.
- Local payments are simulated, and currency rates are fixed test values.
- Confirmation emails aren't sent yet.
- Ticket supply of 1 is enforced by the service. Event issuers stay active so they can keep minting.
- Stellar resets its testnet periodically, which can remove older transactions from explorers.

Next steps

- Deploy the application and add the public URL to this report.
- Merge the work and add the repository evidence.
- Begin the customer development plan in Section 9.
- Build the mobile ticket view and organizer gate scanner.
- Apply for a payment provider account and prepare for mainnet.

Appendix A: Testnet transactions

All 24 orders from the final end-to-end run. Each transaction opens on StellarExpert.
